

**P-TYPE QUANTUM-WELL-BASE BIPOLAR TRANSISTOR DEVICE  
EMPLOYING INTERDIGITATED BASE AND EMITTER FORMED WITH A  
CAPPING LAYER**

**CROSS-REFERENCE TO RELATED APPLICATION**

This application is a continuation-in-part of co-owned U.S. Application Nos. 10/340,941 and 10/340,942, filed on January 13, 2003, herein incorporated by reference in their entirety.

**BACKGROUND OF THE INVENTION**

**1. Field of the Invention**

This invention relates broadly to field of semiconductor devices (and associated fabrication methodology) and, in particular, to semiconductor devices (and associated fabrication methodology) that utilize modulation doped quantum well heterojunctions to realize optoelectronic/electronic devices.

**2. State of the Art**

Modulation-doped quantum well heterojunction transistors - including well known Pseudomorphic Pulsed Doped High Electron Mobility Transistors (Pulsed Doped PHEMT), which are sometimes referred to as Pulsed Doped Modulation Doped Field Effect Transistors (Pulsed Doped MODFET) or Pulsed Doped Two Dimensional Gas Field Effect Transistors (Pulsed Doped TEGFET) - have become well recognized for their superior low noise and high frequency performance and are now in demand in many high frequency applications (e.g., front end amplifier in wireless communications systems and in Monolithic Microwave and Millimeterwave IC (MMIC) designs).

1        GaAs/InGaAs/Al<sub>x</sub>Ga<sub>1-x</sub>As is the III-V material system of choice for these devices  
2 because of the ability to grow high optical/electrical quality epitaxial layers by molecular  
3 beam epitaxy (MBE). Alternatively, strained silicon heterostructures employing silicon-  
4 germanium (SiGe) layers have been used to produce such devices.

5  
6        U.S. Patent No. 4,827,320 to Morkoc et al. discloses a pseudomorphic HEMT  
7 (PHEMT) structure that employs a layer of strained InGaAs (undoped) between a GaAs  
8 substrate and a layer of undoped AlGaAs to form a quantum well (QW) defined by the  
9 strained InGaAs layer. A layer of n+ doped AlGaAs is formed on the undoped AlGaAs  
10 layer. A layer of n+ GaAs is formed on the layer of n+ doped AlGaAs. The layer of n+  
11 GaAs facilitates an ohmic contact to source/drain electrodes. A gate electrode of  
12 aluminum is recessed below the layer of n+ GaAs and a portion of the n+ AlGaAs layer  
13 by wet chemical etch and evaporation of aluminum.

14  
15        The PHEMT structure has been very successful in producing microwave  
16 transistors that operate well into the multi-gigahertz regime, initially being used  
17 extensively in military systems and now finding their way into commercial products,  
18 particularly in the area of cellular communications. In recent years, there has been a  
19 growing interest in combining the PHEMT with optical capability because of the  
20 difficulty in propagating very high frequency signals to and from the integrated circuit by  
21 coaxial lines. Combining electronic with optoelectronic components monolithically gives  
22 rise to the concept of the optoelectronic integrated circuit (OEIC). However, there are  
23 serious problems encountered because of the dissimilar nature of the structures of the  
24 FET, the pn junction laser, PIN diode, etc.

25  
26        To achieve this goal, inversion channel heterojunction structures created from a  
27 single epitaxial growth have been used to realize a range of optoelectronic devices  
28 including lasers, detectors and field effect transistors (FETs). An exemplary inversion  
29 channel heterojunction structure is described in Taylor and Kiely, "Theoretical and  
30 Experimental Results for the Inversion Channel Heterostructure Field Effect Transistors",  
31 IEE Proceedings-G, Vol. 140, No. 6, December 1993. In this structure, for the region

1 between the modulation doping layer and the gate of the semiconductor surface, the  
2 doping of this region is substantially p type in order to provide a low resistance ohmic  
3 contact for the gate of the FET.

4  
5 However, the high p-type doping of this region creates many problems, including:

6 i) the effects of free carrier absorption makes formation of a vertical cavity  
7 laser difficult;

8 ii) forming a depletion-type FET by implanting n-type dopant is difficult;  
9 this difficulty stems from the difficulty in controlling the dopant density in the bulk  
10 region; more specifically, compensating a large p density with a large n density to obtain  
11 a lower p density is difficult to control in a bulk region (but much easier in a delta doped  
12 region);

13 iii) controlling the threshold voltage of an enhancement type FET is  
14 difficult because the input capacitance is a function of doping which is harder to control  
15 than layer thickness; and

16 iv) producing effective current funneling for inducing lasing is difficult;  
17 more specifically, it is very desirable to create a pn junction by N type implantation to  
18 steer the current in this structure since this would be compatible with the overall approach  
19 to building the FET devices; the heavy p doping bulk layers makes it difficult to create  
20 junction isolation that has low leakage.

21  
22 Heterojunction Bipolar Transistor (HBT) devices have also been developed for  
23 high frequency applications. An HBT device includes a base layer structure disposed  
24 between an emitter layer structure and a collector layer structure. The base layer  
25 structure may utilize a graded composition (as described in U.S. Patent 6,037,616) or a  
26 modulation doped QW structure (as described in U.S. Patent 5,003,366). A transferred-  
27 substrate process may be used wherein the emitter is epitaxially grown on a substrate, and  
28 the collector is epitaxially grown on the top of the sample. By depositing the collector as  
29 a small feature on the top surface of the sample and etching a collector mesa, a minimum  
30 collector capacitance is realized. At this point, the sample is flipped and mounted on a  
31 low resistance ground plane, and the substrate below the emitter is removed by etching so

1 that processing of the emitter and base can begin in a conventional manner from the top  
2 side. An exemplary transferred-substrate process for HBTs is described in D. Mensa et  
3 al., "Transferred-substrate HBTs with 254 GHz  $F_T$ ," Electron. Lett., April 1999, 35(7),  
4 pp. 605-606. These prior art devices provide for improved current gain and cutoff  
5 frequency with respect to prior art silicon bipolar transistors. However, it is difficult to  
6 realize a range of optoelectronic devices (including lasers, detectors, FET devices,  
7 waveguide devices) from the epitaxial growth that is used to form such HBT devices.

## 8 9 SUMMARY OF THE INVENTION

10  
11 It is therefore an object of the invention to provide a bipolar transistor device  
12 suitable for high frequency applications that can be used to realize within a single  
13 integrated circuit chip a wide range of optoelectronic devices (including lasers, detectors,  
14 FET devices, complementary HFET devices with n-channel and p-channel control  
15 elements respectively, etc).

16  
17 It is another object of the invention to provide such a bipolar transistor device  
18 with reduced base resistance and capacitance as well as reduced emitter resistance and  
19 capacitance to thereby improve the frequency response characteristics of the device.

20  
21 In accord with these objects, which will be discussed in detail below, a high  
22 performance bipolar transistor device is realized from a series of layers formed on a  
23 substrate, the series of layers including a first set of one or more layers each comprising  
24 n-type dopant material, a second set of layers forming a p-type modulation doped  
25 quantum well structure, and a third set of one or more layers each comprising n-type  
26 dopant material. The first set of layers includes an n-type ohmic contact layer. A  
27 collector terminal metal layer is deposited and patterned on one layer of the third set. On  
28 both sides of the collector terminal metal layer, p-type ion implant regions and a  
29 patterned base terminal metal layer (which contact the p-type modulation doped quantum  
30 well structure) are formed in an interdigitated manner with respect to a patterned emitter  
31 metal layer formed on the n-type ohmic contact layer. Preferably, a capping layer that

1 covers the sidewalls of the active device structure as well as the collector metal layer is  
2 used to form the interdigitated base and emitter metal layers of the device. These features  
3 reduce the base resistance and capacitance as well as reduce the emitter resistance and  
4 capacitance and thus enable higher frequency operation. One or more of the metal layers  
5 of the device are preferably formed from a composite metal structure (such as a NiInW  
6 composite metal structure) that is transformed into a low resistance metal layer by a  
7 rapid-thermal anneal operation.

8  
9 Additional objects and advantages of the invention will become apparent to those  
10 skilled in the art upon reference to the detailed description taken in conjunction with the  
11 provided figures.

#### 12 BRIEF DESCRIPTION OF THE DRAWINGS

13  
14  
15 FIG. 1A is a cross-sectional schematic showing the generalized construction of an  
16 exemplary p-type quantum-well-base bipolar transistor in accordance with the present  
17 invention;

18  
19 FIG. 1B is a pictorial illustration of an exemplary configuration of the p-type  
20 quantum-well-base bipolar transistor device of FIG. 1A;

21  
22 FIG. 1C is a graph showing the generalized current-voltage characteristics of the  
23 p-type quantum-well-base bipolar transistor device of FIG. 1A and 1B;

24  
25 FIG. 2A is a schematic showing an exemplary layer structure made with group  
26 III-V material in accordance with the present invention, and from which bipolar transistor  
27 devices of the present invention can be made;

28  
29 FIG. 2B shows the energy band diagram of the structure of FIG. 2A;

FIGS. 3A - 10 are schematic views of the structure of FIG. 2A during fabrication of an exemplary p-type quantum-well-base transistor from such structure; FIG. 3A is a cross-sectional schematic view of the structure showing the formation of the collector metal layer; FIG. 3B is an elevational schematic view of the collector metal layer; FIG. 4 is an elevational schematic view of the interdigitated base and emitter metal layer that is disposed on opposite sides of the collector metal layer; FIGS. 5A and 5B are cross-sectional schematic views of the structure showing the mesas upon which is formed the base metal layer and the emitter metal layer, respectively; FIGS. 6A and 6B are cross-sectional schematic views that show a capping layer (preferably a nitride film) that covers the mesas of FIGS. 5A and 5B as well as the active device structure; FIGS. 7A and 7B are cross-sectional schematic views that shows the result of a directional etching operation that exposes mesa areas for metal contact formation thereto; FIGS. 8A, 8B, 9A and 9B are cross-sectional schematic views that show the formation of the base metal layer and the emitter metal layer, respectively; and FIG. 10 an elevational schematic view of the completed device, including the interdigitated base and emitter metal layers.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention builds upon novel device structures utilizing modulation-doped QW heterojunctions that do not suffer from the problems associated with the prior art PHEMT devices and HBT devices. Such novel device structures are described in detail in the following patent references: U.S. Patent 6,031,243; U.S. Patent Application No. 09/556,285 (Attorney Docket No. OPE-002), filed on April 24, 2000; U.S. Patent Application No. 09/798,316 (Attorney Docket No. OPE-004), filed on March 2, 2001; U.S. Patent Application No. 08/949,504 (Attorney Docket No. OPE-005), filed on October 14, 1997, U.S. Patent Application No. 10/200,967 (Attorney Docket No. OPE-005-CIP), filed on July 23, 2002; U.S. Application No. 09/710,217 (Attorney Docket No. OPE-006), filed on November 10, 2000; U.S. Patent Application No. 60/376,238 (Attorney Docket No. OPE-008-PROV), filed on April 26, 2002; and U.S. Application No. 10/280,892 (Attorney Docket No. OPE-012), filed on October 25, 2002; each of these references herein incorporated by reference in its entirety.

Turning now to FIG. 1A, a multi-layer sandwich structure in accordance with the present invention, and from which devices of the present invention can be made, includes a bottom dielectric distributed bragg reflector (DBR) mirror 12 formed on a substrate 10. The bottom DBR mirror 12 typically is formed by depositing pairs of semiconductor or dielectric materials with different refractive indices. When two materials with different refractive indices are placed together to form a junction, light will be reflected at the junction. The amount of light reflected at one such boundary is small. However, if multiple junctions/layer pairs are stacked periodically with each layer having a quarter-wave ( $\lambda/4n$ ) optical thickness, the reflections from each of the boundaries will be added in phase to produce a large amount of reflected light (e.g., a large reflection coefficient) at the particular center wavelength  $\lambda_D$ . Deposited upon the bottom DBR mirror 12 is the active device structure which consists of a p-type modulation doped quantum well structure 20 sandwiched between a bottom n-type region (layers 14,16) and a top n-type region 49. An undoped spacer layer 18 is disposed between the bottom n-type region and the p-type modulation doped quantum well structure 20. An undoped spacer layer 22 is disposed between the p-type modulation doped quantum well structure 20 and the top n-type region 49.

More particularly, the bottom n-type ohmic contact layer(s) 14 enables the formation of ohmic contacts thereto, such as the emitter terminal electrodes 60A, 60B. Deposited on layer 14 are one or more n-type layer(s) 16. Preferably, the doping of layer(s) 16 is such that it should not be depleted in any range of operation of the device, i.e. the total doping in this layer should exceed the total doping charge contained in the modulation doped layer of the p-type modulation doped QW structure 20 described below. This layer 16 also serves optically as a small part of the lower waveguide cladding for optical devices realized in this structure. Note that a majority of the lower waveguide cladding is provided by the lower DBR mirror 12 itself. Deposited on layer 16 is an undoped spacer layer 18. Layers 14, 16 and 18 serve electrically as part of the emitter of the p-type quantum well base bipolar transistor. In this configuration, layer 14 achieves low contact resistance for the emitter.

1  
2 Deposited on layer 18 is a p-type modulation doped QW structure 20 that defines  
3 one or more quantum wells (which may be formed from strained or unstrained  
4 heterojunction materials) that serve electrically as part of base of the p-type quantum well  
5 base bipolar transistor. Deposited on the p-type modulation doped QW structure 20 is an  
6 undoped spacer layer 22 followed by an n-type region 49. The undoped spacer layer 22  
7 and the n-type region 49 serve electrically as part of the collector of the p-type quantum  
8 well base bipolar transistor. The n-type region 49 provides an ohmic contact for the  
9 collector terminal electrode 62 of the p-type quantum well base bipolar transistor.

10  
11 For the p-type quantum well base bipolar transistor, base terminal electrodes 58A,  
12 58B are operably coupled to opposite sides of the p-type QW structure 20, emitter  
13 terminal electrodes 60A, 60B are operably coupled to opposite sides of the n-type contact  
14 layer 14, and a collector terminal electrode 62 is operably coupled to the top n-type  
15 region 49 of the device. Preferably, the base terminal electrode 58A and emitter terminal  
16 electrode 60A on the one side of the device have an interdigitated structure, while the  
17 base terminal electrode 58B and emitter terminal electrode 60B on the other side of the  
18 device also have an interdigitated structure. Such interdigitated structures decrease the  
19 base terminal resistance as well as the emitter terminal resistance.

20  
21 In addition, as will be discussed in detail hereinafter with reference to FIGS. 2A -  
22 9, the device is preferably formed with a capping layer that is deposited to cover the  
23 active device structure prior to metallization of the base terminal electrodes and the  
24 emitter terminal electrodes. This capping layer, which is preferably a nitride film,  
25 enables the base and emitter metal layer pattern to be moved in a lateral direction closer  
26 to the active device structure, which also decreases the base terminal resistance and the  
27 emitter terminal resistance. By decreasing such resistance values, the transconductance  
28 ( $g_m$ ) and cutoff frequency of the device is increased. In this manner, the device can be  
29 used in higher frequency applications.

30

FIGS. 1B and 1C illustrate the operational characteristics of the p-type quantum-well-base bipolar transistor device of FIG. 1A. Under normal operation, the base terminal electrodes 58A, 58B are forward biased with respect to the emitter terminal electrodes 60A, 60B by a voltage level  $V_{BE}$ , and the collector terminal electrode 62 is forward biased with respect to the emitter terminal electrodes 60A, 60B by a voltage level  $V_{CE}$  as shown in FIG. 1B. For small values of  $V_{CE}$ , the device operates in the saturation region where the current  $I_C$  varies in a quasi-linear manner with respect to  $V_{CE}$  as shown in FIG. 1C. For larger values of  $V_{CE}$ , the device operates in the constant current region where the current  $I_C$  is substantially constant with respect to  $V_{CE}$  as shown in FIG. 1C.

The p-type quantum well base bipolar transistor is preferably integrated with one or more other devices, including transistor devices (such as n-type quantum well base bipolar transistors, complementary HFET transistors), optoelectrical devices (such as resonant cavity lasers, detectors, modulators, optical amplifiers) and passive optical devices (such as waveguides). Preferably, such devices are realized from the inversion quantum-well channel device structures as described in detail in the patent references incorporated by reference above. With these structures, a single fabrication sequence is used to make the devices, including the electrical devices (e.g., transistors) and the optoelectronic devices (e.g., laser/detector/modulator). In other words, a single set of n type and p type contacts, critical etches, dielectric depositions etc. are used to realize these devices simultaneously. The essential features of this device structure include 1) a modulation doped quantum well interface, 2) a refractory metal gate/emitter contact, 3) self-aligned channel contacts formed by ion implantation, 4) n-type metal contacts to the n-type ion implants and the bottom n-type layer, and 5) p-type metal contacts to the p-type layers.

To form a resonant cavity device where light enters into and/or is emitted from the device laterally (i.e., from a direction normal to the cross section of FIG. 1A), a diffraction grating and top dielectric mirror are formed over the active device structure. For resonant cavity lasing devices, the diffraction grating performs the function of

1 diffracting light produced by the resonant cavity into light propagating laterally in a  
2 waveguide which has the top dielectric mirror and bottom DBR mirror as waveguide  
3 cladding layers. For resonant cavity detecting devices, the diffraction grating performs  
4 the function of diffracting incident light that is propagating in the lateral direction into a  
5 vertical mode, where it is absorbed resonantly in the resonant cavity.

6  
7 Alternatively, light may enter (and/or exit) the resonant cavity in a vertical  
8 direction through an optical aperture (not shown) in the top surface (or bottom surface) of  
9 the device. In this case, the diffraction grating is omitted, and the top dielectric mirror  
10 and bottom DBR mirror define a resonant cavity for the vertical emission (and/or  
11 absorption) of light such that the device operates as a vertical cavity surface emitting  
12 laser (detector).

13  
14 The optical path length between the bottom DBR mirror and top dielectric mirror  
15 preferably represents an integral number of  $1/2$  wavelengths at the designated  
16 wavelength. The optical path length is controlled to enable this condition.

17  
18 The epitaxial growth structures described above may be realized with a material  
19 system based on group III-V materials (such as a GaAs/AlGaAs). Alternatively, strained  
20 silicon heterostructures employing silicon-germanium (SiGe) layers may be used to  
21 realize the multilayer structures described herein. FIG. 2A illustrates an exemplary  
22 epitaxial growth structure utilizing group III-V materials for realizing the structure of  
23 FIG. 1A and the optoelectrical/electrical/optical devices formed from this structure in  
24 accordance with the present invention.

25  
26 The structure of FIG. 2A can be made, for example, using known molecular beam  
27 epitaxy (MBE) techniques. As shown, a first semiconductor layer 151 of AlAs and a  
28 second semiconductor layer 152 of GaAs are alternately deposited (with preferably at  
29 least seven pairs) upon a semi-insulating gallium arsenide substrate 149 in sequence to  
30 form the bottom distributed bragg reflector (DBR) mirror 12. The number of AlAs layers  
31 will preferably always be one greater than the number of GaAs layers so that the first and

last layers of the mirror are shown as layer 151. In the preferred embodiment the AlAs layers 151 are subjected to high temperature steam oxidation to produce the compound  $\text{Al}_x\text{O}_y$  so that a mirror will be formed at the designed center wavelength. This center wavelength is selected such that all of the resonant wavelengths for the various cavities of the array will be subject to high reflectivity. Therefore the thicknesses of layers 151 and 152 in the mirror are chosen so that the final optical thickness of GaAs and  $\text{Al}_x\text{O}_y$  are one quarter wavelength of the center wavelength  $\lambda_D$ . Alternatively the mirrors could be grown as alternating layers of one quarter wavelength thickness of GaAs and AlAs at the designed wavelength so that the oxidation step is not used. In that case, many more pairs are required (with typical numbers such as 22 pairs) to achieve the reflectivity needed for efficient lasing.

Deposited upon the mirror is the active device structure which consists of two HFET devices. The first of these is the p-channel HFET (PHFET) 11, which has one or more p-type modulation doped quantum wells and is positioned with the gate terminal on the bottom (i.e. on the mirror 12 just described) and the collector terminal above. The second of these is an n-channel HFET (NHFET) 13, which has one or more n-type modulation doped quantum wells and is positioned with the gate terminal on top and the collector terminal below. The collector region of the NHFET device 13 also functions as the collector region of the PHFET device 11. However, the collector terminal of the NHFET device 13 is a p-type contact to p-type quantum well(s) disposed below (above) the collector region, while the collector terminal of the PHFET device 11 is an n-type contact to n-type quantum well(s) disposed above the collector region. Therefore a non-inverted n-channel device is stacked upon an inverted p-channel device to form the active device structure.

The active-device layer structure begins with layer 153 of N+ type GaAs that enables the formation of ohmic contacts thereto (for example, when contacting to the emitter terminal of a p-type quantum-well-base bipolar device, the cathode terminal of a thyristor device, the gate terminal of an inverted p-channel HFET device, or the sub-collector terminal of an n-channel HFET device). Layer 153 has a typical thickness of

1000-3000 Å and a typical n-type doping of  $3.5 \times 10^{18} \text{ cm}^{-3}$ . The N+ doped GaAs layer 153 corresponds to the ohmic contact layer 14 of FIG. 1A. Deposited on layer 153 is layer 154 of n-type  $\text{Al}_{x1}\text{Ga}_{1-x1}\text{As}$  with a typical thickness of 500-3000 Å and a typical doping of  $1 \times 10^{17} \text{ cm}^{-3}$ . The parameter  $x1$  is preferably in the range between 70% and 80% for layer 154. This layer serves as part of the PHFET gate and optically as a small part of the lower waveguide cladding of the device. Note that a majority of the lower waveguide cladding for waves propagating in the guide formed by the optically active region of the device is provided by the lower DBR mirror itself. The lower DBR mirror causes the light to be guided partially as a dielectric waveguide and partially as a mirror waveguide. Next are 4 layers (155a, 155b, 155c, and 155d) of  $\text{Al}_{x2}\text{Ga}_{1-x2}\text{As}$ . These 4 layers (collectively, 155) have a total thickness about 380-500 Å and where  $x2$  is about 15%. The first layer 155a is about 60-80 Å thick and is doped N+ type in the form of delta doping. The second layer 155b is about 200-300 Å thick and is undoped. The third layer 155c is about 80 Å thick and is doped P+ type in the form of delta doping. The fourth layer 155d is about 20-30 Å thick and is undoped to form a spacer layer. This layer forms the lower separate confinement heterostructure (SCH) layer for the laser, amplifier and modulator devices. The n-type AlGaAs layer 154 and n-type AlGaAs layer 155a correspond to the n-type layer(s) 16 of FIG. 1A, and the undoped AlGaAs layer 155b corresponds to the undoped spacer layer 18 of FIG. 1A.

The next layers define the quantum well(s) that form the inversion channel(s) during operation of the PHFET 11. For a strained quantum well, this includes a spacer layer 156 of undoped GaAs that is about 10-25 Å thick and then combinations of a quantum well layer 157 that is about 40-80 Å thick and a barrier layer 158 of undoped GaAs. The quantum well layer 157 may be comprised of a range of compositions. In the preferred embodiment, the quantum well is formed from an  $\text{In}_{0.2}\text{Ga}_{0.8}\text{AsN}$  composition with the nitrogen content varying from 0% to 5% depending upon the desired natural emission frequency. Thus, for a natural emission frequency of  $0.98 \mu\text{m}$ , the nitrogen content will be 0%; for a natural emission frequency of  $1.3 \mu\text{m}$ , the nitrogen content will be approximately 2%; and for a natural emission frequency of  $1.5 \mu\text{m}$ , the nitrogen content will be approximately 4-5%. The well barrier combination will typically be

1 repeated (for example, three times as shown), however single quantum well structures  
 2 may also be used. Unstrained quantum wells are also possible. Following the last barrier  
 3 of undoped GaAs is a layer 159 of undoped  $\text{Al}_{x_2}\text{Ga}_{1-x_2}\text{As}$  which serves electrically as part  
 4 of the collector of the PHFET device 11 and is about  $0.5\mu\text{m}$  in thickness. All of the  
 5 layers grown thus far form the PHFET device 11 with the gate contact on the bottom.  
 6 The layers between the P+ AlGaAs layer 155c and the last undoped GaAs barrier layer  
 7 158 correspond to the p-type modulation doped heterojunction QW structure 20 of FIG.  
 8 1A. Undoped AlGaAs layer 159 corresponds to the undoped spacer layer 22 of FIG. 1A.

9

10 Layer 159 also serves electrically as part of the collector of the NHFET device 13.  
 11 Deposited on layer 159 are two layers (collectively 160) of undoped GaAs of about 200-  
 12  $250\text{ \AA}$  total thickness, which form the barrier of the first n-type quantum well. Layer 160  
 13 is thicker than the normal barrier layer of about  $100\text{ \AA}$  because it accommodates the  
 14 growth interruption to change the growth temperature from  $610^\circ\text{C}$  (as required for  
 15 optical quality  $\text{Al}_{x_2}\text{Ga}_{1-x_2}\text{As}$  layers) to about  $530^\circ\text{C}$  for the growth of InGaAs. Therefore  
 16 layer 160 includes a single layer 160a of about  $150\text{ \AA}$  and a barrier layer 160b of about  
 17  $100\text{ \AA}$ . The next layer 161 is the quantum well of  $\text{In}_{0.2}\text{Ga}_{0.8}\text{As}$ , which is undoped and  
 18 about  $40\text{-}80\text{ \AA}$  in thickness. It is noted that the n-type quantum well layer 161 need not  
 19 be of the same formulation as the p-type quantum well layer 157. The barrier layer 160b  
 20 of  $100\text{ \AA}$  and quantum well layer 161 may be repeated, e.g., three times. Then there is a  
 21 barrier layer 162 of about  $10\text{-}30\text{ \AA}$  of undoped GaAs which accommodates a growth  
 22 interruption and a change of growth temperature. Next there are four layers (collectively  
 23 163) of  $\text{Al}_{x_2}\text{Ga}_{1-x_2}\text{As}$  of about  $300\text{-}500\text{ \AA}$  total thickness. These four layers (163) include  
 24 a spacer layer 163a of undoped  $\text{Al}_{x_2}\text{Ga}_{1-x_2}\text{As}$  that is about  $20\text{-}30\text{ \AA}$  thick, a modulation  
 25 doped layer 163b of N+ type doping of  $\text{Al}_{x_2}\text{Ga}_{1-x_2}\text{As}$  (with doping about  $3.5 \times 10^{18}\text{ cm}^{-3}$ )  
 26 that is about  $80\text{ \AA}$  thick, a spacer layer 163c of undoped  $\text{Al}_{x_2}\text{Ga}_{1-x_2}\text{As}$  that is about  $200\text{-}$   
 27  $300\text{ \AA}$  thick, and a P+ type delta doped layer 163d of  $\text{Al}_{x_2}\text{Ga}_{1-x_2}\text{As}$  (with doping about  
 28  $3.5 \times 10^{18}\text{ cm}^{-3}$ ) that is about  $60\text{-}80\text{ \AA}$  in thickness. Layers 163b and 163d form the top  
 29 plate and bottom plate of a parallel plate capacitor which forms the field-effect input to  
 30 all active devices. The doping species for layer 163d is preferably carbon (C) to ensure  
 31 diffusive stability. In contrast to layer 163b which is always depleted, layer 163d should

never be totally depleted in operation. For the optoelectronic device operation, layer 163 is the upper SCH region. The layers between the undoped GaAs barrier layer 160a and the N+ AlGaAs layer 163b provide an n-type modulation doped heterojunction QW structure 24. Undoped AlGaAs layer 163c corresponds to the undoped spacer layer 26 of FIG. 1A.

One or more layers (collectively 164) of p-type  $\text{Al}_{x1}\text{Ga}_{1-x1}\text{As}$  are deposited next to form part of the upper waveguide cladding for the laser, amplifier and modulator devices. Note that a majority of the upper waveguide cladding for waves propagating in the guide formed by the optically active region of the device is provided by an upper dielectric mirror as described below. The upper dielectric mirror causes the light to be guided partially as a dielectric waveguide and partially as a mirror waveguide. Preferably, layer 164 has a thickness on the order of 500-1500 Å, and includes a first thin sublayer 164a that is 10-20 Å thick and has a P+ doping of  $10^{19} \text{ cm}^{-3}$  and a second sublayer 164b that is 700 Å thick and has a P doping of  $1 \times 10^{17} - 5 \times 10^{17} \text{ cm}^{-3}$ . The parameter  $x1$  of layer 164 is preferably about 70%.

Deposited next is an ohmic contact layer 165 (which may comprise a single layer of GaAs or a combination of GaAs (165a) and InGaAs (165b) as shown). Layer 165 is about 50-100 Å thick and is doped to a very high level of P+ type doping (about  $1 \times 10^{20} \text{ cm}^{-3}$ ) to enable formation of ohmic contacts thereto (for example, when contacting to the anode terminal of a thyristor device).

Alternatively, the active device structure may be described as a pair of stacked quantum-well-base bipolar transistors formed on the bottom DBR mirror (layers 151/152). The first of these is an p-type quantum-well-base bipolar transistor (comprising layers 153 through 159) which has one or more p-type modulation doped quantum wells and is positioned with the emitter terminal on the lower side (i.e. on the bottom mirror as just described) and the collector terminal on the upper side. The second of these is an n-type quantum-well-base bipolar transistor (comprising layers 159 through 165b) which has one or more n-type modulation doped quantum wells and is positioned

1 with the emitter terminal on the top side and the collector terminal on the lower side  
2 which is the collector of the p-type quantum-well-base bipolar transistor. Therefore a  
3 non-inverted n-channel device is stacked upon an inverted p-channel device to form the  
4 active device structure. In this configuration, the bottom n-type layers (layers 153  
5 through 155a) and the undoped spacer layer 155b serve electrically as part of the emitter  
6 of the p-type quantum-well-base bipolar transistor (as well as part of the cathode of a  
7 thyristor device), the p-type QW structure (layers 155c through 158) serves electrically as  
8 part of the base of the p-type quantum-well-base bipolar transistor, and spacer layer 159  
9 serves electrically as part of the collector of the p-type quantum-well-base bipolar  
10 transistor (as well as part of the collection of an n-type quantum-well-base bipolar  
11 transistor). The n-type QW structure (layers 160a through 163b) serves electrically as  
12 part of the base of an n-type quantum-well-base bipolar transistor. The top p-type layers  
13 (layers 163d through 165b) and the undoped spacer layer 163c serve electrically as part  
14 of the emitter of the n-type quantum-well-base bipolar transistor as well as part of the  
15 anode of the thyristor device.

16  
17 FIG. 2B shows the energy band diagram of the structure of FIG. 2A.

18  
19 To form a resonant cavity device where light is input into and emitted from the  
20 device laterally (i.e., from a direction normal to the cross section of FIG. 2A), a  
21 diffraction grating (for example, as described in detail in U.S. Patent 6,031,243) and top  
22 DBR mirror is formed over the active device structure described above. For vertical  
23 cavity lasing devices, the diffraction grating performs the function of diffracting light  
24 produced by the vertical cavity into light propagating laterally in a waveguide which has  
25 the top DBR mirror and bottom DBR mirror as waveguide cladding layers and which has  
26 lateral confinement regions (typically formed by implants as described herein in more  
27 detail). For vertical cavity detecting devices, the diffraction grating performs the function  
28 of diffracting incident light that is propagating in the lateral direction into the vertical  
29 cavity mode, where it is absorbed resonantly in the vertical cavity.

1           Alternatively, light may enter and exit the resonant vertical cavity vertically  
2 through an optical aperture in the top surface of the device. In this case, the diffraction  
3 grating is omitted, the top DBR mirror defines a cavity for the vertical emission and  
4 absorption of light, and the device operates as a vertical cavity surface emitting  
5 laser/detector. The distance between the top DBR mirror and bottom DBR mirror  
6 preferably represents an integral number of  $1/2$  wavelengths at the designated  
7 wavelength. Preferably, the thickness of layer 164 and/or layer 159 is adjusted to enable  
8 this condition.

9  
10           The structure of FIGS. 2A and 2B may also be used to realize various transistor  
11 devices (including p-type quantum-well-base bipolar transistors, n-type quantum-well-  
12 base bipolar transistors, n-channel HFET devices, p-channel HFET devices) as well as  
13 waveguide devices as described in detail in the patent references incorporated by  
14 reference above.

15  
16           FIGS. 3A through 9 illustrate cross-sectional views and elevational views of the  
17 multilayer structure of FIG. 2A during the fabrication of an exemplary p-type quantum-  
18 well-base bipolar transistor. The operations begin by implanting n-type ions, which  
19 preferably comprise silicon ions through the top p-type structure (layers 163d through  
20 layer 165b). The n-type implanted ions may include impurities, such as silicon fluoride  
21 molecules, which aid in reducing the activation temperature for the implanted ions. The  
22 n-type implanted ions are subsequently activated by a rapid-thermal-anneal (RTA)  
23 operation as described below to form an n-type region 49. The n-type implant region 49  
24 serves electrically as part of the collector of the p-type quantum well base bipolar  
25 transistor, and thus will be covered by collector metal layer 174 as described below.  
26 Preferably, the N-type implant region 49 extends to a depth near layer 162 as shown in  
27 FIG. 3A. In this configuration, layers 159 through 162 correspond to the undoped spacer  
28 layer 22 of FIG. 1A for the p-type quantum well base bipolar transistor.

29  
30           A metal layer 174 and capping layer 181 are deposited and defined over the n-  
31 type implant region 49. The capping layer 181, which preferably comprises a silicon

1 nitride film, covers the metal layer 174 as shown in FIG. 3A. The metal layer 174 forms  
2 the collector terminal as best shown in the elevational view of FIG. 3B. Preferably, the  
3 metal layer 174 comprises a composite metal structure formed by depositing Nickel (Ni),  
4 Indium (In) and Tungsten (W) metals, which is transformed during an RTA operation as  
5 set forth below into a thermally-stable low resistance metal layer in contact with the n-  
6 type implant region 49. Exemplary NiInW composite metal structures are described in  
7 Murakami et al., "Thermally stable ohmic contacts to n-type GaAs. VIII Sputter-  
8 deposited InAs contacts," J. Appl. Physics, Vol. 68, No. 5, 1990, pgs. 2475-2481; and  
9 Hallili et al., "Thermally stable ohmic contacts to n-type GaAs. IX. NiInW and  
10 NiIn(Mn)W Contact Metals," J. Appl. Physics, Vol. 70, No. 12, 1991, pgs. 7443 -7448,  
11 herein incorporated by reference in their entireties. Such composite metal structures  
12 include an InAs/W multilayer structure, an InAs/Ni/W multilayer structure, an  
13 Ni/InAs/Ni/W multilayer structure, and Ni/Ni-In/Ni/W multilayer structure (where the  
14 Ni-In layer is formed by codeposition of Ni and In). In the preferred embodiment of the  
15 present invention, the same composite metal structure is used to form low resistance  
16 metal contact layers to both the n-type and p-type GaAs conduction channels of the  
17 device.

18  
19 The resultant structure is subjected to patterning and etching operations that  
20 expose two sets of interdigitated mesa regions 183, 185 on each side of the collector  
21 metal layer 174 as shown in FIG. 4. The mesa regions 183 are formed at (or near) layer  
22 158 as shown in FIG. 5A, and the mesa regions 185 are formed at (or near) layer 153 as  
23 shown in FIG. 5B. The mesa regions 183 are used to form contacts to the p-type QW  
24 structure (layers 155c through 158) as part of the base terminal electrode of the device.  
25 The mesa regions 185 are used to form contacts to the bottom n-type ohmic contact layer  
26 153 as part of the emitter terminal electrode of the device. Preferably, a mask covers the  
27 capping layer 181 (and the metal layer 174 thereunder) during a directional plasma  
28 etching operation that forms sidewalls that extend from the edges of the top capping layer  
29 181 down in a substantially-vertical direction to the mesa regions 183 and 185.

1 P-type ions are implanted into the mesa regions 183 on both sides of the collector  
2 metal layer 174. When activated, the p-type ions form p-type implant regions 171 as  
3 shown in FIG. 5A. Advantageously, the p-type implant regions 171 are self-aligned by  
4 the collector metal layer 174 as shown. The p-type ions used for the p-type implant  
5 regions 171 may comprise magnesium ions and possibly phosphorous ions.  
6 Alternatively, the p-type ions may comprise beryllium (and possibly other impurities,  
7 such as fluorine, that control diffusion of the p-type ions during RTA activation).  
8 Moreover, other impurities, such as manganese, may be implanted in conjunction with  
9 the p-type ions in order to lower the potential barrier between the composite metal  
10 structure of layer 188 and the p-type implant regions 171 upon thermal transformation as  
11 described below.

12  
13 The resultant structure is then covered with a capping layer 187 as shown in  
14 FIGS. 6A and 6B. The capping layer 187 is preferably realized by a nitride film.

15  
16 The capping layer 187 is then subject to a directional plasma etching operation  
17 that removes portions of the capping layer 187 over the mesa regions 183, 185 as shown  
18 in FIGS. 7A and 7B. The directional plasma etching operation also removes portions of  
19 the capping layer 187 that covers the top capping layer 181. Importantly, the top capping  
20 layer 181 (or portions thereof) remains in place to protect against shorts between the  
21 metal layer 174 and the metal layers 189, 191 as described below.

22  
23 The resultant structure is then covered with a metal layer 188 as shown in FIGS.  
24 8A and 8B. Preferably, the metal layer 188 comprises a composite metal structure  
25 formed by depositing Nickel (Ni), Indium (In) and Tungsten (W) metals. For those  
26 portions of the NiInW composite metal structure that interface to the p-type implant  
27 regions 171, such NiInW composite metal portions are transformed during an RTA  
28 operation as set forth below into a thermally-stable low resistance metal layer in contact  
29 with the p-type implant regions 171. Similarly, for those portions of the NiInW  
30 composite metal structure that interface to the n-type contact layer 153, such NiInW  
31 composite metal portions are transformed during an RTA operation as set forth below

1 into a thermally-stable low resistance metal layer in contact with the n-type contact layer  
2 153. In this manner, the same NiInW composite metal structure is used to form low  
3 resistance metal contact layers to both the n-type and p-type GaAs conduction channels  
4 of the device. Exemplary NiInW composite metal structures are described in the articles  
5 to Murakami et al. and Hallili et al., which are incorporated by reference above. Such  
6 composite metal structures include an InAs/W multilayer structure, an InAs/Ni/W  
7 multilayer structure, an Ni/InAs/Ni/W multilayer structure, and Ni/Ni-In/Ni/W multilayer  
8 structure (where the Ni-In layer is formed by codeposition of Ni and In).

9  
10 The device structure is then subjected to an RTA operation on the order of 800°C  
11 to 900°C (or greater). The RTA has two primary purposes. First, it activates all of the  
12 implants to form the n-type implant region 49 and the p-type implant regions 171.  
13 Secondly, it transforms the composite metal structure of layers 174 and 188 to form low  
14 resistance metal contact layers to both the n-type and p-type conduction channels of the  
15 device. Also note that during the RTA, the metal composite layers 174 and 188 provide  
16 barrier layers to out-diffusion of the particular implanted ion species that underlies such  
17 layers.

18  
19 The metal layer 188 is then patterned and etched to form the base terminal  
20 electrode portions 189 and the emitter terminal electrode portions 191 of the p-type  
21 quantum-well-base bipolar transistor device. The base terminal electrode portions 189  
22 cover the mesa regions 183 and corresponding p-type implants 171 as shown in FIG. 9A.  
23 The emitter terminal electrode portions 191 cover the mesa regions 185 at the n-type  
24 contact layer 153 as shown in FIG. 9B. In addition, the device is isolated from other  
25 devices by an etch down to the semi-insulating substrate 149, which includes an etch  
26 through the mirror pairs 151/152 of AlAs/GaAs as shown in FIGS. 9A and 9B.

27  
28 Preferably, the metal layer 188 is patterned by a wet etchant that removes only  
29 those portions of the metal layer 188 that overlie the capping layer 187 (these portions do  
30 not interface to the p-type and n-type contacts of the device layers and are not  
31 transformed during RTA). The wet etchant does not react with those portions of the

metal layer 188 that interface to the p-type and n-type contacts of the device layers (and which are transformed to a low resistance contact metal structure during RTA). An example of such a wet etchant suitable for use with the exemplary NiInW composite metal structures is sold by the Transene Company under the name TFG. Note that during the RTA, the Ni/Ni-In/Ni/W composite structure that overlies the GaAs-based layers of the mesa regions 183,185 interacts with the GaAs layers thereunder to transform part of the composite structure adjacent to such mesa regions 183,185 to InGaAs. The wet etchant does not attack these InGaAs structures yet attacks the Ni-based composite structures that overlie the capping layer 187, thus leaving behind the InGaAs structures as an appropriate ohmic contact (p-type for base, or n-type for emitter) to the underlying GaAs layers. Preferably, the isolation etch down to the semi-insulating substrate 149 is accomplished by a directional plasma etching operation.

Finally, the device may be oxidized in a steam ambient to convert layers 151 to AlO, which form the bottom DBR mirror. During this oxidation step, the exposed sidewalls of the etched AlGaAs layers are passivated by the formation of very thin layers of oxide. In addition, dielectric layers (not shown) are deposited to form the top DBR mirror for resonant cavity devices as described below. Preferably, the dielectric layers comprise SiO<sub>2</sub> and a high refractive index material such as GaAs, Si, or GaN.

A plan schematic view of the resultant p-type quantum well base bipolar transistor device is shown in FIG. 10. Note that the process methodology described above enables the offset (in the lateral direction) between the active device structure and the base metal layer pattern 189 and the emitter metal layer pattern 191, respectively, to substantially correspond to the thickness of the capping layer 187. Preferably, the thickness of the capping layer 187 can be made small (on the order of 200Å to 500 Å ). By reducing this offset, the base terminal resistance and the emitter terminal resistance are decreased. By decreasing such resistance values, the transconductance ( $g_m$ ) and cutoff frequency of the device is increased. In this manner, the device can be used in higher frequency applications.

1 For a high performance p-type quantum-well-base bipolar transistor device, it is  
2 preferable that the effective area of the base-collector junction in addition to the effective  
3 area of the base-emitter junction be minimized. This reduces the base-collector  
4 capacitance and the base-emitter capacitance, and thus provides for higher frequency  
5 operation. Moreover, it is preferable that the resistance of the base terminal, the  
6 resistance of the collector terminal and the resistance of the emitter terminal be  
7 minimized to provide for higher frequency operation.

8  
9 In the p-type quantum-well-base bipolar transistor device of FIGS. 3 through 10,  
10 the effective area of the base-collector junction is controlled by the dimensions of the  
11 collector electrode metal layer 174. The resistance of the collector is minimized by  
12 controlling the doping concentration of the collector contact (N+ implant 49). Finally,  
13 the effective area of the base-emitter junction in addition to the base terminal resistance  
14 and emitter terminal resistance are minimized by interdigitization of the P+-type implants  
15 171/base electrode portions 189 with respect to the emitter electrode portions 191 on both  
16 sides of the collector metal layer 174. As shown in FIGS. 5A through 9A, the P+  
17 implants 171 are formed in selected areas on both sides of the collector metal layer 174.  
18 Importantly, these implants 171 are deep to a point near the dielectric layer 151, which  
19 reduces the effective area of the base-emitter junction, and eliminates much of the  
20 capacitance between the base and the emitter (e.g., the capacitance is reduced to that  
21 which exists along the sidewalls of the implants 171). Advantageously, the finger  
22 regions of metal layers 189/191 that are part of the base terminal electrode 58 and emitter  
23 terminal electrode 60 as shown in FIG. 10 provide very low base terminal resistance and  
24 emitter terminal resistance, respectively. In addition, because the implants 171 are  
25 self-aligned to the metal layer 174, the width of the metal layer 174 may be minimized  
26 (preferably, to sub-micron widths). All of these features contribute to higher frequency  
27 operation of the device.

28  
29 For high performance quantum-well-base bipolar transistor devices, it is also  
30 preferable that the vertical distance between the QW base and the emitter /collector of the  
31 device be minimized. Such reduced vertical dimensions reduce the transit time delay of

1 charge passing therethrough, and thus provides for higher frequency operation.  
2 Advantageously, the vertical dimension between the n-type ohmic contact layer 153 and  
3 the top electrode metal layer 174 can be made small (e.g., on the order of 370 - 655 Å) to  
4 provide for high frequency operation.

5  
6 There are many advantages gained by the p-type quantum-well-base transistor  
7 device structures described herein including high frequency operation. Moreover, a  
8 broad array of optoelectronic devices and electronic devices can be integrated therewith  
9 to form a monolithic optoelectronic integrated circuit suitable for many diverse  
10 applications. Such devices include an optoelectronic thyristor. The thyristor has unique  
11 properties of sensitive detection in its OFF state and laser emission in its ON state. The  
12 thyristor structure may be used as a digital modulator, a transceiver, an amplifier and a  
13 directional coupler. These devices may be realized as either waveguide or vertical cavity  
14 devices. The vertical cavity construction enables resonant cavity operation of all device  
15 modes. In addition to the multiple optoelectronic devices, a wide array of transistor  
16 devices (including complementary HFET devices and complementary quantum-well-base  
17 bipolar transistors) are implementable.

18  
19 There have been described and illustrated herein several embodiments of a p-type  
20 quantum-well-base bipolar transistor. While particular embodiments of the invention  
21 have been described, it is not intended that the invention be limited thereto, as it is  
22 intended that the invention be as broad in scope as the art will allow and that the  
23 specification be read likewise. Thus, while particular layers have been described with  
24 particular thicknesses and with particular types and strengths of dopings, it will be  
25 appreciated that certain transition layers could be removed and/or additional layers and/or  
26 sublayers could be utilized, and further that the layers could have different thicknesses  
27 and be differently doped. Also, while particular layers have been described with  
28 reference to their percentage content of certain constituents, it will be appreciated that the  
29 layers could utilize the same constituents with different percentages, or other  
30 constituents. Additionally, while particular formation and metallization techniques have  
31 been described, it will be appreciated that the described structures can be formed in other

1 manners, and other metals can be used. For example, it is contemplated that the collector  
2 of the p-type quantum-well-base bipolar transistor device of FIGS. 3 through 10 can be  
3 formed by etching away portions of the top of multilayer structure of FIG. 2A prior to  
4 implantation of the n-type implant 49 and metallization of the collector metal pattern.  
5 These operations are similar to those described in detail in U.S. Application Nos.  
6 10/340,941 and 10/340,942, filed on January 13, 2003, incorporated by reference above  
7 in their entirety. Further, while particular arrangements of bipolar transistors (as well as  
8 FET transistors, optical emitters, detectors, modulators, amplifiers, etc. formed from the  
9 described semiconductor structure) have been described, it will be appreciated that other  
10 devices can be made from the provided structure and components. It will therefore be  
11 appreciated by those skilled in the art that yet other modifications could be made to the  
12 provided invention without deviating therefrom.
